AB - J02222798 Excess sludge formed in the treatment of sewage is oxidised by O3 as the pretreatment.

In the pretreatment system air (or O2) passed through a filter is sent to an ozoniser through a compressor and a water removing device. O3 generated in the ozoniser is sent to an ejector and excess sludge stored in a tank is fed to the ejector by a pump and then fed to a reactor with O3. In the reactor, the sludge is contacted with O3 for a predetermined time to be oxidised and then to anaerobic digestion process. Gas sepd., is fed through an ozone meter to a treatment equipment of exhuast O3, where remaining O3 is treated, and then released to the air. Amt. of O3 generated in the ozoniser is controlled based on the concn. measured by the ozone meter so that the concn. of remaining O3 is almost zero.

ADVANTAGE - By the pretreatment, concn. of soluble organic substances in the excess sludge is increased. Amt. of O3 generated is controlled. (4pp Dwg.No.0/2)
